- We do not update the parameters if classification is correct
- For misclassified examples, we try to minimize

$$\mathsf{E}(w) = -\sum_{i} w \mathbf{x}_{i} \mathbf{y}_{i}$$

where i ranges over all misclassified examples

· Perceptron algorithm updates the weights such that

$$w \leftarrow w - \eta \nabla \mathsf{E}(w)$$
$$w \leftarrow w + \eta \mathbf{x}_i y_i$$

for a misclassified example ($\boldsymbol{\eta}$ is the learning rate)

Perceptron Logistic Regression More than two cl

 $logistic(x) = \frac{1}{1 + e^{-x}}$

• The perceptron was developed in late 1950's and early 1960's (Rosenblatt 1958)

Logistic Regression More than two class

- It caused excitement in many fields including computer science, artificial intelligence, cognitive science
- The excitement (and funding) died away in early 1970's (after the criticism by Minsky and Papert 1969)

Perceptron Logistic Regression More than two classes

· The main issue was the fact that the perceptron algorithm cannot handle problems that are not linearly separable

Perceptron Logistic Regression More than two of

Logistic regression

C. Cöltekin, SfS / University of Tübinger

- Logistic regression is a classification method
- In logistic regression, we fit a model that predicts P(y|x)• Logistic regression is an extension of linear regression
- it is a member of the family of models called generalized linear models
- Typically formulated for binary classification, but it has a natural extension to multiple classes
- The multi-class logistic regression is often called maximum-entropy model (or max-ent) in the NLP literature

Summer Semester 2017 13 / 26

Summer Semester 2017 15 / 26

• What is P(y|x = 2)?

• Is RMS error appropriate?

Fixing the outcome: transforming the output variable

Instead of predicting the probability p, we predict logit(p)

Perceptron Logistic Regression More than two classes

$$\hat{y} = \text{logit}(p) = \log \frac{p}{1-p} = w_0 + w_1 x$$

- + $\frac{p}{1-p}$ (odds) is bounded between 0 and ∞
- $\log \frac{p}{1-p}$ (log odds) is bounded between $-\infty$ and ∞
- we can estimate logit(p) with regression, and convert it to a probability using the inverse of logit

$$\hat{p} = \frac{e^{w_0 + w_1 x}}{1 + e^{w_0 + w_1 x}} = \frac{1}{1 + e^{-w_0 - w_1 x}}$$

which is called logistic function (or sometimes sigmoid function, with some ambiguity).

Perceptron Logistic Regression More than two class

How to fit a logistic regression model

Reminder:

$$P(y = 1|x) = p = \frac{1}{1 + e^{-wx}}$$
 $P(y = 0|x) = 1 - p = \frac{e^{-wx}}{1 + e^{-wx}}$

The likelihood of the training set is,

$$\mathcal{L}(\boldsymbol{w}) = \prod_{i} P(\boldsymbol{y}_{i} | \boldsymbol{x}_{i}) = \prod_{i} p^{\boldsymbol{y}_{i}} (1-p)^{1-\boldsymbol{y}_{i}}$$

In practice, maximizing log likelihood is more practical:

Perceptron Logistic Regression More than tw

$$\begin{split} \log \mathcal{L}(\boldsymbol{w}) &= \sum_{i} y_{i} \log p + (1 - y_{i}) \log(1 - p) \\ \nabla \log \mathcal{L}(\boldsymbol{w}) &= \sum_{i} (y_{i} - \frac{1}{1 + e^{-wx}}) x_{i} \end{split}$$

- Bad news: there is no analytic solution
- · Good news: the (negative) log likelihood is a convex function
- We can use iterative methods such as gradient descent to find parameters that maximize the (log) likelihood
- Using gradient descent, we repeat

 $\boldsymbol{w} \leftarrow \boldsymbol{w} - \alpha \nabla J(\boldsymbol{w})$

until convergence, α is called the *learning rate*

Perceptron Logistic Regression More than two classes

More than two classes

- Some algorithms can naturally be extended to multiple labels
- · Others tend to work well in binary classification
- Any binary classifier can be turned into a k-way classifier by
 - training k one-vs.-rest (OvR) or one-vs.-all (OvA) classifiers.
 - Decisions are made based on the class with the highest confidence score.
 - This approach is feasible for classifiers that assign a weight or probability to the individual classes
 training k(k-1)/2 one-vs.-one (OvO) classifiers. Decisions are
 - training $\frac{k(k-1)}{2}$ one-vs.-one (OvO) classifiers. Decisions are made based on majority voting

Ç. Çöltekin, SfS / University of Tübingen

Summer Semester 2017 23 / 26

Perceptron Logistic Regression More than two classes

Multi-class logistic regression

- Generalizing logistic regression to more than two classes is straightforward
- We estimate,

$$P(C_k|\mathbf{x}) = \frac{e^{w_k \mathbf{x}}}{\sum_j e^{w_j \mathbf{x}}}$$

Where C_k is the kth class. j iterates over all classes.

- The function is also known as the *softmax* funciton, used frequently in neural network models as well
- This model is also known as a *log-linear model*, Maximum entropy model, Boltzman machine

Logistic regression as a generalized linear model Short divergence to statistics

Logistic regression is a special case of *generalized linear models* (GLM). GLMs are expressed with,

$$g(\mathbf{y}) = \mathbf{X} \mathbf{w} + \mathbf{\varepsilon}$$

- The function g() is called the $\mathit{link\,function}$
- $\boldsymbol{\varepsilon}$ is distributed according to a distribution from *exponential family*
- For logistic regression, g() is the logit function, ε is distributed binomially

C. Cöltekin, SfS / University of Tübingen

Perceptron Logistic Regression More than two classes

One vs. Rest

- For 3 classes we fit 3 classifiers separating one class from the rest
- Some regions of the feature space will be ambiguous
- We can assign labels based on probability or weight value, if classifier returns one
- One-vs.-one and majority voting is another option

Ç. Çöltekin, SfS / University of Tübingen

Summer Semester 2017 24 / 26

Perceptron Logistic Regression More than two classes

Summary

- We discussed two basic classification techniques: perceptron and logistic regression
- We left out many others: Naive Bayes, SVMs, decision trees, ...
- We will discuss some (non-linear) classification methods later

Next

- Fri n-grams (continued)
- Mon tokenization, normalization, segmentation
- Wed More machine leaning
